

Resources/Data/Expeditions Working Group

High-level Summary of Current Activities

- Expeditions
 - Biodiversity: significant improvements in Lifemapper utility and portability
 - Student Challenge, Demo
 - Lake Ecology: Network Overlay (IPOP) + Condor + GLEON.
 - PRAGMA-ENT: First experiments now able to run. Testbed evolution.
- Technology Development
 - Personal Cloud Controller - multi-site virtual cluster creation via enhanced PCC-HTCondor (VM GAHP) and Condor DAG capabilities. IPOP integration
 - Fingerprinting Applications to discover Software dependencies. Demo
- Support
 - Virtual Cluster Allocated @ UCSD for Cyberlearning Expedition

Virtual Biodiversity Expedition

Lifemapper/Rocks update

Goal

Prepare Lifemapper components to be deployed alone or together to work on user-defined and restricted data, i.e. licensed satellite data and sensitive occurrence data for Mount Kinabalu, Sabah, Malaysia

Activities

- Generalize Lifemapper code
- Create installation process
 - Simplify configuration
 - Create installation scripts
 - Automate deployment
- Deploy at institution
- Deploy on a laptop for fieldwork and teaching
- Learn to work together efficiently
 - Meet in person for debugging sessions
 - Maintain ongoing conversation to improve process
 - Repeat mantra: [Don't jump to conclusions](#)

Virtual Biodiversity Expedition

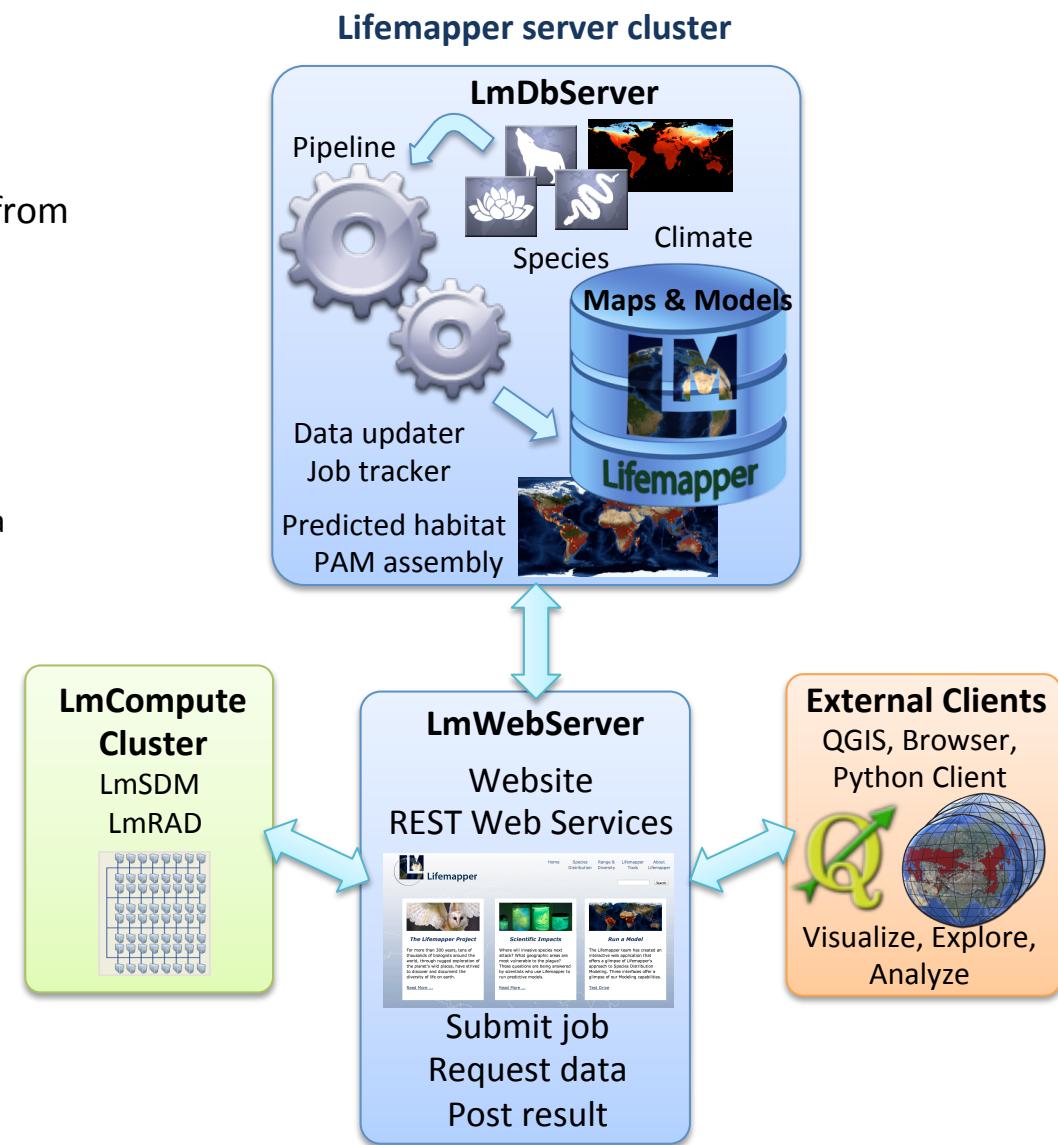

Lifemapper/Rocks update

Goals

- Decouple LmDbServer and LmWebServer from KU-specific implementation
- Automate install and configure process
- Bootstrap database
 - Automate database definition
 - Automate static input data seeding
- Run job pipeline on LmDbServer
 - Read and insert dynamic input species data
 - Create job-chain for each input species
- Deploy and connect LmCompute
 - Request jobs from LmWebServer
 - Calculate jobs
 - Return results to LmWebServer

People

KU: Aimee Stewart
UCSD: Nadya Williams

Virtual Biodiversity Expedition

Lifemapper/Rocks update

Accomplishments

- Run all Lifemapper components outside of KU
- Create Lifemapper component ISOs for remote installations
- Deploy in 2 virtualization tools
 - KVM: 2 clusters
 - rocks-201 as a compute component
 - rocks-204 as server component
 - VirtualBox:
 - Run a 2-node cluster
 - frontend as a server + LmCompute component
 - compute node as LmCompute for executing the jobs.
 - Time from VM import to running pipeline ~1 hr (includes data import and seeding)
- Run Lifemapper Server for student challenge

VirtualBox installation:
Lifemapper web page for computed projections

A screenshot of a Linux desktop environment. At the top, there's a standard window manager bar with icons for Applications, Places, System, and a menu. A terminal window titled 'fe611 [Running]' is open, showing a command-line interface. Below it, a Firefox browser window is titled 'Lifemapper List Service - Mozilla Firefox'. The address bar shows 'fe.public/services/projections'. The main content area of the browser displays a table titled 'Lifemapper List Service' with three columns: 'Id', 'Title', and 'Modification Time'. The table lists various biological names and their dates of modification. At the bottom of the browser window, a message from Firefox states: 'Firefox automatically sends some data to Mozilla so that we can improve your experience.' and 'Choose What I Share'. The taskbar at the bottom of the screen shows several other open applications.

PRAGMA-GLEON Expedition Goals

- Beginning to learn how an extreme ecosystem phenomenon – algal blooms – is expressed in observational data from sensor networks
 - And just how computationally challenging reproducing those events in model simulations can be
- We apply PRAGMA technologies to tackle distributed computing in an innovative way
 - Enabling the community to pool together resources across institutional boundaries, and allowing researchers to continue to use a computer environment they are used to
 - Distributed HTCondor Windows pool connected by IPOP virtual network overlay

People

- U. Wisconsin
 - Paul Hanson, Craig Snortheim
- Virginia Tech
 - Cayelan Carey, Jon Doubek
- U. Florida
 - Renato Figueiredo, Ken Subratie, Youna Jung

Activities

- Close collaboration
 - Computer science and lake ecology researchers
 - Student engagement; excursion (this PRAGMA)
 - Community engagement: GLEON'16 workshop
- Documentation
 - How-tos, installation and use; GitHub Wiki
- IPOD development and deployment
 - Windows service, packaging, XMPP service
- HTCondor integration
 - Generation of HTCondor submit files for GLM model

Accomplishments

- Deployment and documentation of Windows HTCondor pool and IPOB overlay
 - Manager+workers at UF (growing to 48 cores)
 - Submit+workers at Uwisc and VT
 - <https://github.com/GRAPLE/documentation/wiki>
- Will present demonstration at this PRAGMA
- Joint workshop at GLEON'16

PRAGMA 27

PRAGMA Experimental Network Testbed (ENT)

Maurício Tsugawa (UF)
Kohei Ichikawa (NAIST)

ENT Goals

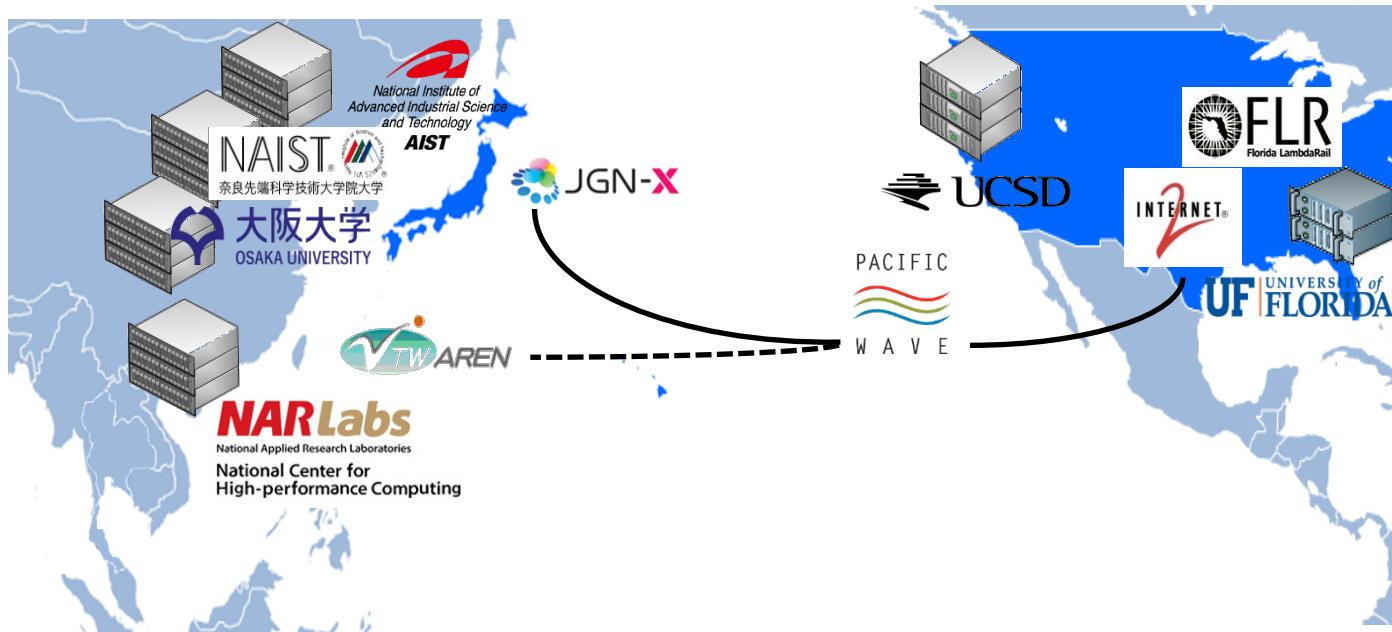

- Build a breakable international SDN testbed for use by PRAGMA researchers
 - By no means a production system
 - Complete freedom to access and configure network resources
- Provide access to SDN hardware/software to PRAGMA researchers
- Offer networking support for PRAGMA multi-cloud and user-defined trust envelopes

ENT Members

- University of Florida
 - Maurício Tsugawa
- Osaka University
 - Shinji Shimojo
 - Susumu Date
 - Yasuhiro Watashiba
 - Yoshiyuki Kido
- Nara Institute of Science and Tech
 - Kohei Ichikawa
 - Pongsakorn U-chupala
 - Chawanat Nakasan
- University of California, San Diego
 - Phil Papadopoulos
 - Luca Clementi
- Advanced Industrial Science and Tech
 - Atsuko Takefusa
 - Yoshio Tanaka
 - Jason Haga
- Indiana University
 - Jim Williams
 - Jennifer Schopf
- National Institute of Information and Communications Technology
 - Jin Tanaka
 - Hiroaki Yamanaka
- Jilin University
 - Xiaohui Wei
- Computer Network Information Center – Chinese Academy of Sciences
 - Ren Young Mao
 - Kejun Dong
- National Center for High-performance Computing
 - Fang-Pang Lin
 - Te-Lung Liu
 - Li-Chi Ku
- Kasetsart University
 - Putchong Uthayopas

ENT Activities

- ENT Backbone
 - VLANs allocated, mapped, and peered (FLR, Internet2, JGN-X, and Pacific Wave), connecting UF, UCSD, NAIST, AIST, and Osaka U.
 - TWAREN to be configured soon.

ENT Activities

- Controllers and applications
 - Rocks provisioning through ENT
 - Network slicing technology (AutoVFlow by H. Yamanaka) being evaluated in ENT
 - Virtual cluster across ENT to run dock (DEMO)
 - Controller for multipath routing (DEMO)

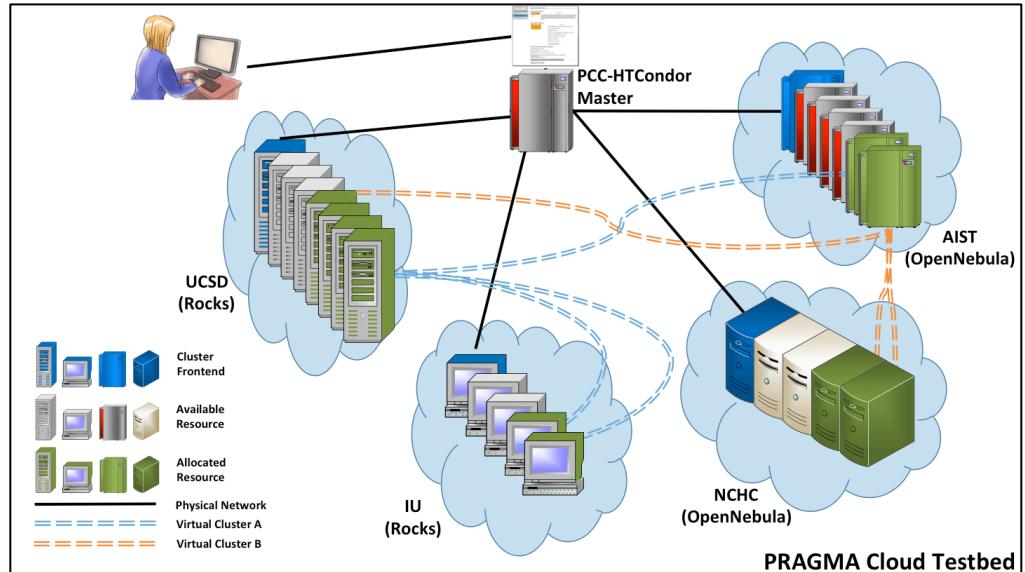

ENT Accomplishments

- ENT backbone live
 - Layer 2 connectivity between UF, UCSD, NAIST, AIST, and Osaka U.
 - Alternative paths established through GRE tunneling for multipath routing research
- Successful “remote” provisioning
 - Rocks front-end at UCSD provisioning a node at UF
- OpenFlow Controllers and Applications under development

Personal Cloud Controller (PCC)

(Yuan Luo, Shava Smallen, Beth Plale, Philip Papadopoulos)

- Goals:
 - Enable lab/group to easily manage **application virtual clusters** on available resources
 - Leverage PRAGMA Cloud tools: `pragma_bootstrap`, `IPOP`, `ViNE`.
 - Lightweight, extends HTCondor from U Wisc.
 - Provide command-line and Web interfaces
- Working Group: Resources

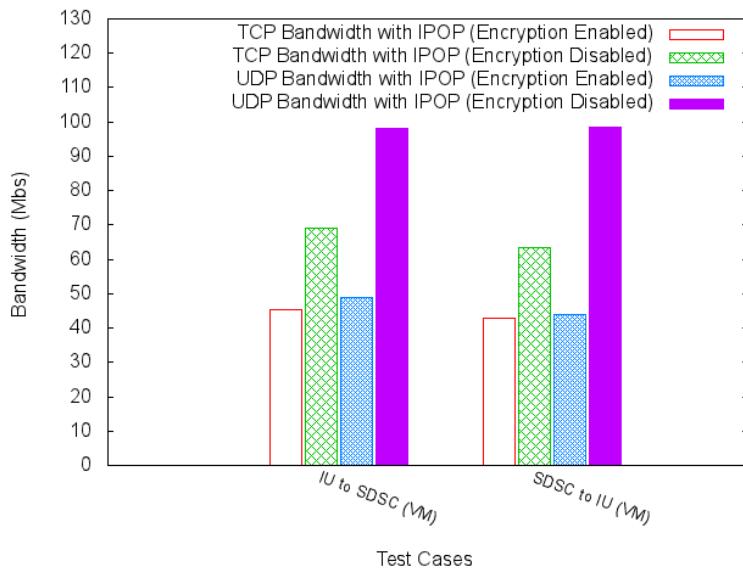

`pragma_boot`

PCC Activities and Accomplishments

(since April 2014)

- Experimented with IPOB and measured initialization and bandwidth performance between IU and SDSC
- Drafted a paper “A Personal Cloud Controller Framework” for submission.

A Personal Cloud Controller Framework

Abstract—User controllability, cloud interoperability and information sharing between resources are application requirements for distributed cloud computing environments. The personal cloud controller (PCC) addresses these requirements by providing a unified interface for managing the personal cloud cluster life-cycle in a fault-tolerant manner. A research effort has been conducted that factors in resource specifications and application requirements to build a personal cloud controller. The PCC extends HTCondor and integrates IPOB to build the network overlay. Experimental results show that the overall PCC framework can efficiently manage the execution of running applications over IPOB is acceptable due to the minimum overhead.

Keywords: Cloud computing, Controllability, HTCondor, PCC, PRAGMA

L. INTRODUCTION

Cloud computing is widely used in business and scientific settings to cost-effectively manage large-scale distributed environments to process large datasets. In this paper we present a personal cloud controller (PCC) that provides user controllability, cloud interoperability and resource-application interoperability. The direct motivation of application of PCC is to facilitate management of resources and optimize the performance of scientific applications in a multi-institutional academic cloud, PRAGMA Cloud [1]. The PRAGMA Cloud infrastructure is distributed and distributed, with resources from multiple institutes from the Pacific Rim and United States. The PRAGMA Cloud is composed of three different clusters, cloud, cluster and hardware architectures. PCC enables users to author their own application virtual machine (VMs) using their preferred VM platforms and then deploy these VMs on demand to one or more of the three different clusters. The three main capabilities of PCC are described below.

User Controllability: A user (application) takes full control of their allocated resources and easily manages the lifecycle of their applications. There is a gap between managing resources by resource providers and utilizing resources by applications, which is often closed later by system administrators. In order to eliminate the gap, a personal cloud controller needs to be in place to maintain controllability of the resources and applications. The system needs to be smart so that resource status and application deployment information are collected and recorded to enable easy management and fast iteration.

Cloud Interoperability: Cloud consumers use their data and services across multiple cloud providers using a unified management interface. A researcher typically has access to several clusters of nodes a user can allocate at once, which consists of a small number of nodes and a limit on the maximum number of nodes a user can allocate at once. Since application requirements grow, the number of resources, single-cloud solutions grow increasingly inadequate. Aggregating these isolated clusters into a single cloud provider allows a researcher to access data and jobs that have access to large datasets stored across multiple locations and geographies. For instance, scientific communities within PRAGMA share data from multiple locations and need to be able to better utilize data distribution information, notably, data locality, to optimize the performance of data-intensive jobs.

Resource Application Interoperability: In order to perform resource allocation and application execution efficiently, information needs to be shared bi-directionally between resource providers and applications. Resource allocation is a subject that has been discussed in many computing areas, such as operating systems, grid computing, and cloud computing. A resource allocation mechanism tries to guarantee the quality of service (QoS) requirements and to correctly by the provider's infrastructure. To better allocate resources to users and thus minimizing the operational cost of the cloud environment, a resource allocation mechanism should also consider the current state of each resource in the cloud environment. The current Infrastructure-as-a-Service based cloud systems are usually unaware of the QoS requirements of the applications and can allocate resources independently of its application profiles, which can significantly impact performance and security for distributed data-intensive applications.

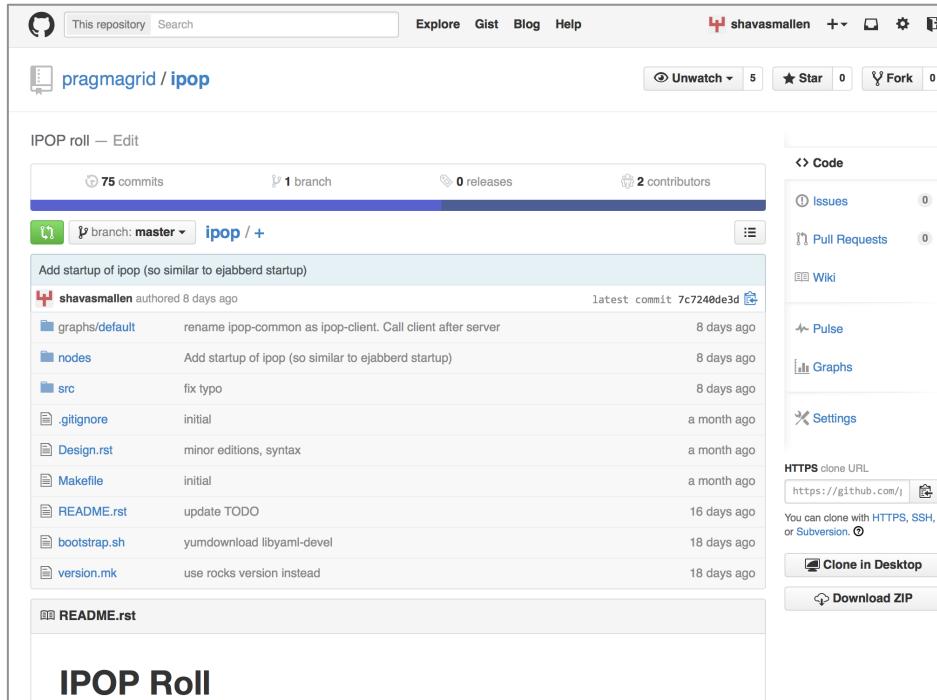

When allocating resources from resource providers, the system applies certain methodologies to achieve optimization goals, such as system utilization, load-balancing, etc. When resources are allocated, another side effect is performed by applications. However, if performed independently, either one of optimization yield optimal performance. In a particular application for instance, two nodes that

PCC Activities and Accomplishments (cont.)

(since April 2014)

- Developed new IPOPO
Rocks roll for easy
installation of IPOPO to any
Rocks virtual cluster

(thanks to Nadya Williams!)
- Added automated IPOPO
server/client initialization
to `pragma_boot`

The screenshot shows the GitHub repository page for `pragmagrid/ipop`. The repository has 75 commits, 1 branch named `master`, 0 releases, and 2 contributors. The `IPOPO Roll` section contains a list of recent commits:

- Add startup of ipop (so similar to ejabberd startup) by shavasmallen 8 days ago
- rename ipop-common as ipop-client. Call client after server by graphs/default 8 days ago
- Add startup of ipop (so similar to ejabberd startup) by nodes 8 days ago
- fix typo by src 8 days ago
- initial by .gitignore 8 days ago
- minor editions, syntax by Design.rst 8 days ago
- initial by Makefile 8 days ago
- update TODO by README.rst 16 days ago
- yumdownload libyaml-devel by bootstrap.sh 18 days ago
- use rocks version instead by version.mk 18 days ago

```
Usage: pragma_boot [-v] [-d] [--basepath path] --list [options] | --vcname vcname [options]

Options:
  --version          show program's version number and exit
  -h, --help          show this help message and exit
  --basepath=BASEPATH The base path used to find all the cluster images
                      (default is /opt/pragma_boot/vm-images)
  -v, --verbose       Print all debugging information to stdout
  -d, --debug         Print only the command that will be executed do not
                      execute them
  --list              list available virtual machines
  --vcname=VCNAME    The name of the cluster which should be started

List Options:
  Options for --list command

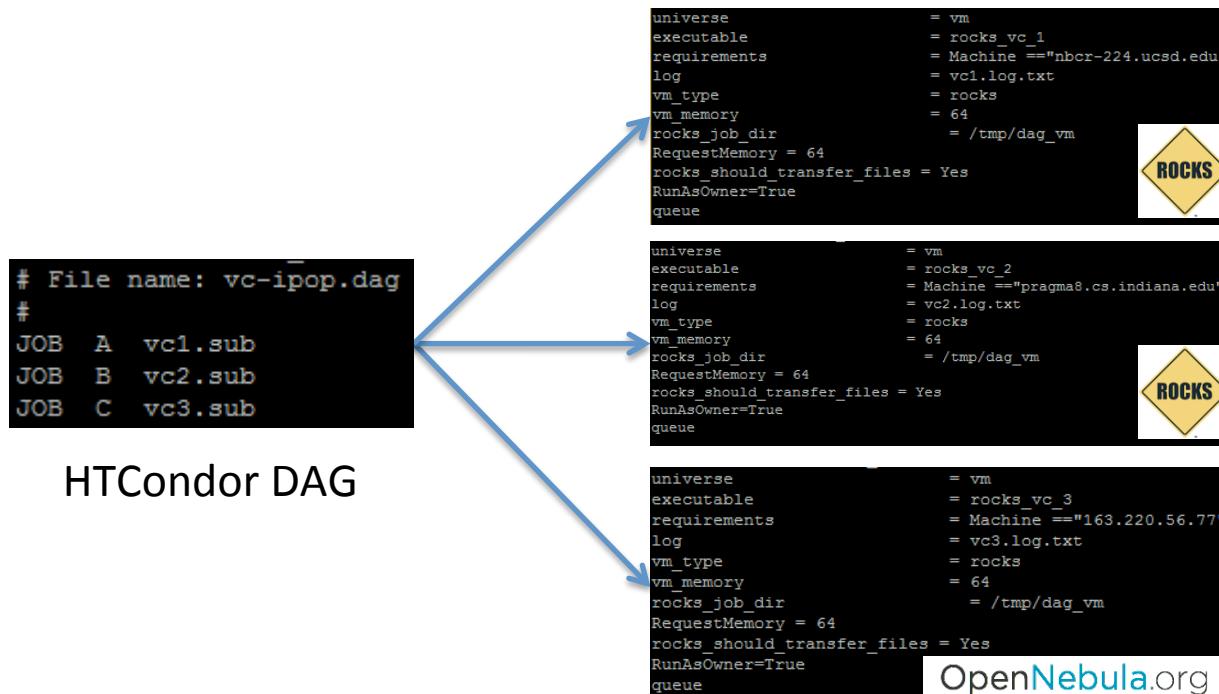

Create Options:
  Options for --vcname command

  --key=KEY           The ssh key that will be authorized on the frontend of
                      the cluster (default is /root/.ssh/id_rsa.pub)
  --num_cpus=NUM_CPUS The number of cpus requested to start up (default is 0
                      only frontend will be started)
  --enable-ipop-client=IPOP_CLIENTINFO_FILE
                      Start up the IPOP-enabled virtual cluster as an IPOP
                      client (to another virtual cluster) using the provided
                      IPOP server info file
  --enable-ipop-server=IPOP_SERVERINFO_FILE
                      Start up the IPOP-enabled virtual cluster with the
                      frontend serving as an IPOP server; once
                      initialization is complete, store the IPOPserver info
                      into the provided path
```

PCC Activities and Accomplishments (cont.)

(since April 2014)

- Enabled multi-site virtual cluster creation via enhanced PCC-HTCondor (VM GAHP) and Condor DAG capabilities
 - Will demo between SDSC, IU, and AIST

Parallel pragma_boot jobs
